# **Key Drivers Analysis**

There are probably many things you would like to improve about your organization. Since it is unlikely that you are going to get the resources to address them all, the challenge to you as a manager is to use your limited resources where they will do the most good. So how do you know where they will do the most good? Where can you "get the most bang for your buck?" One way to determine that is via a key driver analysis.

A key driver analysis, sometimes known as an importance - performance analysis, is a study of the relationships among many factors to identify the most important ones. A key driver analysis can be used in many applications. One of the most common, and a good example for us to use, is in the area of customer satisfaction and loyalty.

**For example:** There are many metrics you can measure about agent performance in a call center that may have some bearing on customer satisfaction. Some of these include

- Agent technical knowledge
- Agent courtesy and friendliness
- speed with which the call was answered
- number of calls required to get a problem solved
- Agent's language skill
- Agent's patience

You can conduct a customer satisfaction survey and ask your customers how they felt about each of these qualities of the agent with whom they dealt. At the same time, you ask them how satisfied they were with the experience

## Importance Performance Maps

The beauty of a key driver analysis is that it can help you understand what your customers feel is important to them having a good experience with your call center. By doing an analysis of their answers and correlating their satisfaction level answer to their rating of each agent performance metric you can derive which factors have the greatest impact on the customer's perceived level of satisfaction.

Key Drivers algorithm classifies the aspects measured in the survey into four categories

- Not important but highly rated
- Not important and poorly rated
- Important and highly rated
- Important and poorly rated

You can then plot this data in a scatter diagram called a key driver chart or an importance performance map.

## **Key Driver Chart**

A key driver chart plots the results of a key driver analysis in a graphical format that can be quickly read and easily understood. Each agent metric from above is plotted on the graph by its **importance** to the customers' satisfaction (on the x-axis) and your **performance** in that area on the y-axis.

This generates four quadrants. The most important is the lower right quadrant. The items plotted here have high importance to your customers, but your performance in those areas is low. These are the areas where your action will have the biggest impact and generate the greatest improvement in customer satisfaction for the effort expended.

# How does Key Drivers algorithm work?

1. It computes the means of the scores of the items: high mean values indicate a good performance rating; a low mean values indicate a poor rating.

2. It runs a Regression (\*) taking the scores of the items as the independent variables, and the score of the general level of your service as the dependent variable. The values of 'betas' indicate how important the items are.

3. It computes the Z-scores among the means of the scores of the items and among the betas from the Regression:

- a positive mean Z-score for one item indicates that this item received a higher evaluation than the average
- a negative mean Z-score for one item indicates that this item received a lower evaluation than the average
- a positive beta Z-score indicates that this item is more important than the average
- a negative beta Z-score indicates that this item is less important than the average

4. Finally, it draws a scatter plot with both the mean Z-score and the beta Z-score

(\*) The regression can be executed introducing all the independent variables or using a forward method. With the forward method, the scatter plot only shows the variables with the highest level of significance.

(\*) The regression can be executed introducing all the independent variables or using a forward selection method. With the forward selection method, the scatter plot only shows the variables with the highest level of significance.

This is traditional output/results from the Regression Procedure. We are now going to interpret those results and 'translate' them into "english' (or any other language) so they can be easily interpreted by the end-user (and their internal clients).
